Introduction to Chemistry
Fourth Edition
Nivaldo J. Tro

Chapter 1
The Chemical World

Dr. Sylvia Esjornson
Southwestern Oklahoma State University
Weatherford, OK

Chemistry—
The science that seeks to understand what matter does by studying what atoms and molecules do. Virtually everything around you is composed of chemicals.
1.1  Soda Pop Fizz
Soda pop is composed of tiny particles called *atoms*.

Atoms are very small. A single drop of soda pop contains about one billion trillion \( (1 \times 10^9 \times 10^{12}) \) atoms. Atoms and molecules are tiny particles that compose all common matter. Chemical bonds are the attachments that hold atoms together.
• The atoms are bound together to form several different types of \textit{molecules}.

• Soda pop is a mixture.

• Carbon dioxide molecules
• Water molecules
• Other substances that contribute flavor and color
• Examine the opening figure of this chapter.
• Identify the two molecules.
• Identify each of the atoms within each molecule.
• From a molecular point of view, explain why soda pop fizzes.
• What molecules are inside the bubbles in a glass of soda pop?
A can of soda pop is a chemical mixture. Soda pop consists primarily of sugar, water, and carbon dioxide. The characteristics of sugar molecules produce the sensation of sweetness on our taste buds. The molecules important to fizzing are carbon dioxide and water.
Carbon dioxide molecules consist of three atoms—one carbon and two oxygen—held together in a straight line by chemical bonds. The characteristics of carbon dioxide molecules make carbon dioxide a gas at room temperature.
Water molecules consist of three atoms—one oxygen and two hydrogen—bonded together, but rather than being straight like carbon dioxide, the water molecule is bent. The characteristics of water molecules make water a liquid at room temperature.
Under pressure, gaseous carbon dioxide molecules are forced to remain mixed with liquid water molecules in a sealed container. When the can is opened, the pressure is released, and carbon dioxide molecules escape out of the soda mixture, creating bubbles.
Bubbles in soda pop:
Pockets of carbon dioxide gas molecules escaping out of liquid water.
1.2 Chemicals Compose Ordinary Things

There is nothing you can hold or touch that is not made of chemicals. Chemicals make up virtually everything we come into contact with.
Some popular conceptions limit the idea of chemicals to dangerous poisons or pollutants.
Chemicals compose ordinary things, too.

- The air we breathe
- The water we drink
- Toothpaste, Tylenol, toilet paper
Chemistry explains the properties and behavior of chemicals by helping us understand the molecules that compose them.
1.3 All Things Are Made of Atoms and Molecules

• The most important idea in all of human knowledge: *All things are made of atoms.*

• Richard Feynman (1918–1988), Nobel Prize–winning physicist and popular professor at California Institute of Technology
• A good, simple definition of **chemistry** is the science that tries to understand how matter behaves by studying how atoms and molecules behave.
1.4 The Scientific Method: How Chemists Think

Ways to understand the world:
Chemists use the scientific method—a way of learning that emphasizes observation and experimentation—to produce knowledge as the result of the senses.
• The scientific method stands in contrast to ancient Greek philosophies and medieval applications of them that emphasized reason to produce knowledge as the result of thoughts.
The Scientific Method

- Observations involve measuring or observing some aspect of nature.
- Hypotheses are tentative interpretations of the observations.
- Laws summarize the results of a large number of observations.
- Theories are models that explain and give the underlying causes for observations and laws.
The Scientific Method

• Hypotheses, laws, and theories must be tested and validated by experiment.
• If they are not confirmed, they are revised and tested through further experimentation.
Observation

• Some observations can be made with the naked eye.
• Other observations emerge from experiments that rely on the use of sensitive instrumentation.
• Observation usually involves the measurement or description of some aspect of the physical world.
Antoine Lavoisier (1743–1794), a French chemist, made an observation about the physical world.

- Lavoisier measured the property of mass in the process of combustion.
- The mass of an object is a measure of the quantity of matter within it.
- Combustion means burning.
Lavoisier burned substances in closed containers.

- He measured the mass of each container and its contents before and after burning the substance inside, noting that there was no change in the mass during combustion.
Observations lead scientists to formulate a hypothesis, a tentative interpretation or explanation of the observations.

- A good hypothesis is *falsifiable*, which means that further testing has the potential to prove it wrong.
- Hypotheses are tested by *experiments*, highly controlled observations designed to validate or invalidate hypotheses.
- The results of an experiment may confirm a hypothesis or show it to be mistaken in some way.
- The hypothesis may have to be modified or discarded and replaced by an alternative.
- The new or revised hypothesis must also be tested through further experimentation.
A number of similar observations lead to the development of a **scientific law**, a brief statement that synthesizes past observations and predicts future ones.

• Lavoisier developed the **law of conservation of mass**, which states, “In a chemical reaction matter is neither created nor destroyed.”
One or more well-established hypotheses may form the basis for a scientific **theory**.

- Theories provide a broader and deeper explanation for observations and laws.
- They are models of the way nature is.
- They often predict behavior that extends well beyond the observations and laws on which they are founded.
Classify each statement as an observation, a law, or a theory.

(a) When a metal is burned in a closed container, the mass of the container and its contents does not change.

(b) Matter is made of atoms.

(c) Matter is conserved in chemical reactions.

(d) When wood is burned in a closed container, its mass does not change.
Figure 1.2 The scientific method
Theories are tested and validated by experiments.

• If a law, hypothesis, or theory is inconsistent with the findings of an experiment, it must be revised and new experiments must be conducted to test the revisions.

• Over time, poor theories are eliminated and good theories—those consistent with experiments—remain.
Example: The atomic theory of John Dalton (1766–1844)

- Dalton explained the law of conservation of mass by proposing that all matter was composed of small, indestructible particles called atoms.
- Dalton’s theory was a model of the physical world—it went beyond the laws and observations of the time to explain these laws and observations.
Scientific Theories

• Established theories with strong experimental support are the most powerful pieces of scientific knowledge.
• People unfamiliar with science sometimes say, “That is just a theory,” as if theories were mere speculations.
• Well-tested theories are as close to truth as we get in science.
The idea that all matter is made of atoms is a theory with two hundred years of experimental evidence to support it.

- Modern technology provides recent images, such as this one, of atoms themselves. This image shows the Kanji characters for “atom” written with individual iron atoms on top of a copper surface.
1.5 A Beginning Chemist: How to Succeed

- Chemistry requires curiosity and imagination. You must want to know the why of things.
Chemistry requires calculation.

- *Quantification* involves measurement as part of observation—it is one of the most important tools in science.
- Quantification allows you to specify the difference precisely.
- For example, two samples of water may feel equally hot to your hand, but when you measure their temperatures, you may find that one is 40°C and the other is 44°C.
Chemistry requires commitment.

- You must do your work regularly and carefully.
- If you do, you will succeed.
- You will be rewarded by seeing a whole new world—the world of molecules and atoms.
Note about the text

• Questions: Answers to all questions numbered in blue appear in the Answers section at the back of the book.

• Problems: Note: The exercises in the Problems section are paired, and the answers to the odd-numbered exercises (numbered in blue) appear in the Answers section at the back of the book.
Success as a Beginning Chemist

• You must be curious and imaginative.
• Be willing to do calculations.
• Be committed to learning the material.

• Do your homework.
Chapter 1 in Review

• Matter and Molecules:
  Chemistry is the science that tries to understand what matter does by understanding what molecules do.

• The Scientific Method:
  Chemists employ the scientific method, which makes use of observations, hypotheses, laws, theories, and experiments.

• Law of Conservation of Mass
• Atomic Theory
